

1. **Subquery** is a query nested inside another SQL query (e.g., SELECT, INSERT, UPDATE, DELETE). Types: **Single-row subquery**, **Multiple-row subquery** (using IN, ANY, ALL), **Multiple-column subquery**, **Correlated subquery**, and **Nested subquery**.

2. **Yes**, we can update or delete records using a subquery. Example:

```
DELETE FROM employees WHERE department_id IN (SELECT department_id FROM departments WHERE location = 'Mumbai');
```

This deletes employees working in Mumbai-located departments.

3. **Limitations of Subqueries:**

- Can only return one column when used in SELECT or WHERE (unless using EXISTS).
- Correlated subqueries run row-by-row, reducing performance on large tables.
- Cannot use ORDER BY inside a subquery (except with TOP/LIMIT/ROWNUM).
- Some subqueries can be rewritten as JOINS for better efficiency.
