

Here's a Java program demonstrating all types of constructors:

java

```
class Student {
    String name;
    int age;

    // 1. Default Constructor (no parameters)
    Student() {
        name = "Unknown";
        age = 0;
        System.out.println("Default Constructor Called");
    }

    // 2. Parameterized Constructor (accepts values)
    Student(String n, int a) {
        name = n;
        age = a;
        System.out.println("Parameterized Constructor Called");
    }

    // 3. Copy Constructor (copies another object)
    Student(Student s) {
        name = s.name;
        age = s.age;
        System.out.println("Copy Constructor Called");
    }

    void display() {
        System.out.println("Name: " + name + ", Age: " + age);
    }

    public static void main(String[] args) {
        Student s1 = new Student();           // Default constructor
        s1.display();

        Student s2 = new Student("Alice", 20); // Parameterized constructor
        s2.display();

        Student s3 = new Student(s2);         // Copy constructor
    }
}
```

```
        s3.display();  
    }  
}
```

Output:

text

Default Constructor Called

Name: Unknown, Age: 0

Parameterized Constructor Called

Name: Alice, Age: 20

Copy Constructor Called

Name: Alice, Age: 20
