

How do you render a React component to the DOM?

You use the `ReactDOM.render()` method, passing in the component and the target DOM element. For React 18+, you use `createRoot()` followed by `root.render()` to render the component into the specified HTML element.

What happens once we type "npm start"? Explain the journey from package.json to index.html.

Typing `npm start` reads the `package.json` "scripts" section and executes the start command (usually `react-scripts start`). This launches a development server, bundles the app using Webpack, injects the JavaScript into `index.html` via the `<div id="root">`, and opens the app in your browser.
