

1 How does JSX differ from HTML?

JSX looks similar to HTML but it is actually JavaScript syntax used in React. It allows writing UI structure inside JavaScript and supports dynamic expressions using `{}`.

2 Can browsers understand JSX directly? How is JSX processed?

No, browsers cannot understand JSX directly. JSX is transpiled into regular JavaScript using tools like Babel before being executed in the browser.

3 What are fragments in JSX and how do you use them?

Fragments allow grouping multiple elements without adding extra nodes to the DOM. They are written as `<></>` or `<React.Fragment></React.Fragment>`.

4 How do you handle inline styles in JSX? Provide an example.

Inline styles in JSX are written as JavaScript objects using camelCase properties.

Example:

Hello

5 What are the rules for writing JSX tags? (2–3 lines)

JSX tags must have one parent element. All tags must be properly closed (e.g., `</div>`). Attributes use camelCase (e.g., `className` instead of `class`).

6 What is the purpose of the key attribute in JSX?

The key attribute helps React identify elements in a list. It improves performance by helping React efficiently update and re-render list items.
