

Difference between empty dependency array and omitting the array altogether:

Using `[]` runs the effect only once after the initial render, while omitting the array causes the effect to run after every render.

Handling cleanup in `useEffect` and its necessity:

Cleanup is performed by returning a function from the effect to prevent memory leaks and unwanted behavior, such as canceling subscriptions or timers.

Common pitfalls to avoid when using `useEffect`:

Missing dependencies can lead to stale closures, and incorrect dependency arrays may cause infinite loops or unnecessary re-renders.

Conditionally running effects in `useEffect`:

Place the condition inside the effect itself, as dependency arrays should not contain conditions but only reactive values.
