

## **Yuki: Technical Assignment: Build a Link Checker**

**Deadline:** 24 hours

**Technology:** Any programming language. A command-line tool or simple webpage is sufficient.

### **The problem**

Our team shares links with clients. Sometimes clients report that links don't work. Build a small tool that accepts a list of URLs, checks them, and produces a useful report.

### **Your tool should:**

- Accept multiple URLs through pasted text or a text file.
- Check each URL and show its result with a meaningful explanation.
- Handle invalid URLs, duplicate entries, and websites that don't respond.
- Continue checking the remaining links when one fails.
- Show a summary of the results.

### **Decisions you need to make**

We have deliberately left some details open. Decide what "working" means, how long to wait for a response, and how to handle a link that redirects or requires login. Explain your choices.

### **Submit:**

1. Your source code and instructions to run it.
2. Sample input and the report your tool generated.
3. A short README covering:
  - What questions would you ask us before starting?
  - What assumptions did you make?
  - Which edge cases did you test?
  - Can a link fail in your tool but still work in someone's browser? Why?
  - What would you improve with more time?

You may use AI or other resources; disclose how you used them.

**We will evaluate your reasoning, handling of unexpected situations, and clarity of explanation not visual polish or the number of features.**
